

The Venture Idea

Live-commerce sellers run understaffed shows where one operator has to moderate chat, answer product questions, manage listings, update inventory, and drive conversion in real time. The wedge is an operator copilot that handles chat engagement, guardrailed replies, listing and inventory control, and on-demand product research from a single seller surface.

Specifically, we want to see

Show real-time LLM behavior with grounded retrieval and guardrailed agentic writes against seller catalog data.

Deliverables

1. Working Prototype (main event)

Build a real-time web app that ingests a live chat stream plus seller catalog and product metadata, generates suggested replies and auto-replies gated by guardrails, surfaces listing and inventory actions, and supports on-demand product research with a sub-2 second reply latency target.

Key requirements:

- Chat ingestion with an LLM reply engine grounded in seller catalog, listings, and policies.
- Guardrail layer enforcing price, availability, policy, and tone rules before any send.
- Listing and inventory actions such as push, swap, markdown, or stock adjustment.
- At least one depth area: retrieval and function calling, streaming infrastructure, guardrails for agentic writes, seller UX, or live-commerce workflows.

2. PRD (1-2 pages)

Outline the copilot-to-agentic automation ladder, pilot design with 3-5 eBay Live sellers, MVP module scope, co-build model with eBay, and GMV plus operator-load success metrics.

3. TDD (1-2 pages)

Cover real-time ingestion architecture, catalog grounding and retrieval, guardrail stack, audit trail for agentic writes, latency budgets, eBay API integration, and rollback paths.

The prototype is the main event. PRD and TDD are show-your-work documents. Rough is fine. Use any tools and AI assistants you want. Submit by replying to this email with your Prototype + PRD + TDD. Solution should be submitted within 48 hours of receipt. If you need extra time, let me know and include your anticipated submission date.
